## Abstract

We develop new confidence interval estimators for the underlying mean of a stationary simulation process. These estimators can be viewed as generalizations of Schruben's so-called standardized time series area confidence interval estimators. Various properties of the new estimators are given.

In this note, we present new confidence interval estimators for the underlying mean  $\mu$  of a stationary simulation process. These estimators can be viewed as generalizations of the so-called area estimators given in Schruben (1983) and Goldsman (1984).

Consider the stochastic process  $X_1, \dots, X_m$ . Define

$$\overline{X}_{j} \equiv \frac{1}{j} \sum_{k=1}^{j} X_{k}$$
,  $j=1,\ldots,m$ ,

$$\sigma^2 \equiv \lim_{m \to \infty} m \text{Var}(\bar{X}_m)$$
, and

$$T_{m}(t) \equiv \frac{\left[mt\right](\overline{X}_{m}-\overline{X}_{m}t]}{\sigma\sqrt{m}}, \quad 0 \leq t \leq 1,$$

where [.] is the greatest integer function.  $\{T_m(t), 0 \le t \le 1\}$  is called the standardized time series. Schruben (1983) proves that if  $X_1, \dots, X_m$  is a stationary,  $\varphi$ -mixing, finite variance sequence of random variables (satisfying one other technical condition), then as  $m \to \infty$ ,  $T_m(t)$  converges in distribution to a standard Brownian bridge process,  $\{B_t, 0 \le t \le 1\}$ . Also, the standardized time series is asymptotically independent of  $m\overline{X}_m$ .

Remark: It is well known that  $B_t \sim Nor(0, t(1-t))$  and  $Cov(B_{t_1}, B_{t_2}) = min(t_1, t_2)(1-max(t_1, t_2))$ .

Define  $A \equiv \frac{\sigma}{m} \sum_{k=1}^{m} c_k T_m(k/m)$ , the  $c_k$ 's being pre-specified. For large m,  $A = (is approximately distributed as) <math>\sigma Nor(0,V)$ , where  $V \equiv \frac{1}{2} \sum_{j=1}^{m} \sum_{k=1}^{m} Cov(c_j B_{j/m}, c_k B_{k/m})$ .

It will be computationally convenient to approximate V by letting j = ms and k = mt (so that djdk =  $m^2$ dsdt). Thus,

$$V = \frac{1}{m^2} \sum_{j=1}^{m} \sum_{k=1}^{m} c_j c_k \min(j/m, k/m)[1-\max(j/m, k/m)]$$

$$= \int_{0}^{1} \int_{0}^{1} c_{ms} c_{mt} \min(s,t)[1-\max(s,t)] dsdt$$

$$= 2 \int_{0}^{1} \int_{0}^{t} c_{ms} c_{mt} s(1-t) dsdt .$$
(1)

So  $A^2/V = \sigma^2 x^2(1)$ , and this is called the weighted area estimator for the variance  $\sigma^2$ .

Suppose now that we work with the process  $X_1, \dots, X_n$ , where n=bm, and that this series satisfies Schruben's conditions. Divide the process into b contiguous batches, each of size m; i.e.,  $X_{(i-1)m+1}$ ,  $X_{(i-1)m+2}$ , ...,  $X_{im}$  comprise batch i, i=1,...,b. Each individual batch can be standardized: For i=1,...,b and j=1,...,m, let

$$\bar{X}_{i,j} \equiv \frac{1}{j} \sum_{k=1}^{j} X_{(i-1)m+k}$$
 (average of the first j X's from the i-th batch),

$$\overline{X}_n = \frac{1}{n} \sum_{k=1}^n X_k$$
 (grand mean),

$$T_{i,m}(t) \equiv \frac{\left[mt\right](\bar{X}_{i,m}-\bar{X}_{i,\lfloor mt\rfloor})}{\sigma\sqrt{m}}, 0\leq t\leq 1, \text{ and}$$

$$A_{i} \equiv \frac{\sigma}{m} \sum_{k=1}^{m} c_{k} T_{i,m}^{(k/m)}.$$

For large enough m, each of the standardized time series [the  $T_{i,m}(t)$ 's] is approximately distributed as a Brownian bridge; so  $A_i = \sigma Nor(0,V)$ , i=1,...,b. Further, for large m, we can treat the batches as if they were (approximately) independent. This yields:

$$\frac{1}{V} \sum_{i=1}^{b} A_i^2 = \sigma^2 x^2 (b) .$$

An immediate consequence of Theorem 21.1 of Billingsley (1968) is that

$$Z_{n} \equiv \frac{\overline{X}_{n}^{-\mu}}{\sigma/\sqrt{n}} \approx \text{Nor}(0,1) .$$

Then the asymptotic independence result above gives:

$$\frac{z_n}{\left[\frac{\sum A_i^2}{\sigma^2 b V}\right]^{1/2}} \approx \frac{Nor(0,1)}{\left[\frac{x^2(b)}{b}\right]^{1/2}} \sim t(b).$$

We finally obtain confidence interval estimators for  $\mu$ :

$$\Pr\left\{\mu \in \overline{X}_{n} \pm t_{b,1-\alpha/2} \left[\frac{1}{nbV} \sum_{i=1}^{b} A_{i}^{2}\right]^{1/2}\right\} \approx 1-\alpha, \qquad (2)$$

where  $t_{b,\nu}$  is the upper- $\nu$  quantile of the t(b) distribution.

We consider various choices for the weights (the  $c_k$ 's). These choices and their resulting V's [from the integral approximation (1)] are summarized in Table 1.

### Remarks:

- (i) After choosing the weighting sequence  $\{c_j\}$ , the associated V from Table 1 is used in (2) to form a confidence interval estimator.
- (ii) The calculation of V from (1) is straightforward (but sometimes tedious).

Example: For choice 3 (from Table 1),

$$V : 2 \int_0^1 \int_0^1 \frac{1}{s(1-s)} \frac{1}{t(1-t)} s(1-t) ds dt$$

$$= 2 \int_0^1 \int_0^1 \frac{1}{v(1-s)t} ds dt = -2 \int_0^1 \frac{\ln(1-t)}{t} dt = \frac{\pi^2}{3}.$$

- (iii) The variance estimator which results from choice 1 (the equal weighting case) is asymptotically the same (as  $m + \infty$ ) as the so-called area variance estimator from Schruben (1983).
- (iv) For each standardized time series,  $\{T_{i,m}(m)\}$ , choice 2 grants greater weight for 'small' values of t. Choices 3 through 6 give comparatively little weight to the middle (t  $\approx$  1/2) of each standardized time series.
- (v) Table 2 summarizes an empirical study involving the order 1 exponential autoregressive model [cf. Lewis, (1980)]. The weighted area estimators are seen to perform well for 'large' batch size.
- (vi) Denote the random variable corresponding to the half-length of the weighted area estimator by H. Following Schmeiser (1982) and Goldsman and Schruben (1984) (G-S), it is easy to derive the following:

E[H] = 
$$\frac{\sigma}{\sqrt{n}} t_{b,1-\sigma/2}^{(2/b)} \frac{\Gamma((b+1)/2)}{\Gamma(b/2)}$$
,

$$Var(H) = \frac{\sigma^2}{n} t_{b, 1-\alpha/2}^2 \left\{ 1 - \frac{2}{b} \left[ \frac{\Gamma((b+1)/2)}{\Gamma(b/2)} \right]^2 \right\}, \text{ and}$$

The coverage probability,

mented than some which which is the some of the sound of

$$Pr\{|\bar{X}_n^{-\mu_1}| < H\} = F(t_{b,1-\alpha/2}) - F(-t_{b,1-\alpha/2})$$
, where

 $\Gamma(.)$  is the gamma function and F(.) is the c.d.f. of the noncentral

of correlation amongst batches which are encountered when using the area estimator.
